Abstract: To what extent are factors that are extrinsic to the artwork relevant to judgements of artistic value? One might approach this question using traditional philosophical methods, but one can also approach it using empirical methods; that is, by doing experimental philosophical aesthetics. This paper provides an example of the latter approach. We report two empirical studies that examine the significance of three sorts of extrinsic factors for judgements of artistic value: the causal-historical factor of contagion, the ontological factor of uniqueness, and the contextual factor of appreciative environment.

We explore the context of appreciation by performing studies in a museum as well as the lab. We found that contagion made a difference in both settings. However, uniqueness only made a difference in the lab setting, but not in the museum. This suggests that the context of appreciation may make a difference to judgements of artistic value. Of broader significance, these studies show the value of experimental philosophical aesthetics and the value of doing in situ empirical research on art.
conducted it on site during Grayson Perry’s *The Vanity of Small Differences* exhibit at Temple Newsam House in Leeds, UK. This allowed us to directly explore the effect of the appreciative context on judgements of artistic value.

As is discussed below, the results of our studies are intriguing. The studies confirm previous experimental research which suggests that some extrinsic factors can make a difference to the evaluation of art. In particular, we found that the causal-historical factor of contagion made a difference to judgements of artistic value in both a museum and a lab setting. This is in line with results from previous studies. On the other hand, we did not find that the ontological factor of uniqueness had a univocal effect. Uniqueness made a difference in a lab setting but not in a museum setting. And this difference also suggests that the contextual factor of the appreciative environment may make a difference to judgements of artistic value.

As the reader will see, we also learned a few lessons about doing in situ aesthetic research. We’ll say more about the challenges and prospects of this sort of research. We’ll also say more about the relevance of the experimental results for philosophical thinking about artistic value.

**THEORETICAL BACKGROUND**

**Artistic Value and the Causal-Historical Factor of Contagion**

The dominant view in contemporary philosophical aesthetics is that causal-historical factors such as an artist’s intentions, their achievement, and the art-historical context of creation are relevant to artistic appreciation and evaluation. So, for example, one work of art might be artistically better than another simply in virtue of being a greater achievement. Or a work may possess the artistic value it has because of its relation to, and commentary on, a prior work of art.

In this section, we focus on a different sort of causal-historical factor which has been extensively explored by psychologists but only minimally addressed by philosophers of art: contagion. *Contagion* refers to ‘the belief that, through physical contact, objects can take on a special quality or essence’. Contagion is driven by the psychological mechanism of magical thinking. In turn, contagion influences the evaluation of objects. For example, an object may be thought to be authentic, and hence valuable, insofar as it has acquired some non-physical essence from an individual.

The effect of contagion has been studied in the context of consumer research, in the lab and in the wild. For example, among the collection of the Central Midwest Barry Manilow Fan Club, the most valuable items are ones that ‘actually touched Barry’. The effect of contagion has also been studied in the context of evaluation of art, albeit only in the lab and only focused on judgements about monetary value.

Talk of ‘magical thinking’ may tempt the reader to think that contagion effects on judgements of value are unambiguously irrational and, hence, ir-
relevant. We are, if this is right, led astray when magical thinking affects our judgements about art, as is allegedly manifested in a contagion effect. But this alleged irrationality is not obvious. Carolyn Korsmeyer has recently argued that the ‘transitivity of touch’ (that is, contagion) can be vindicated; that is, she argues that aesthetic concern for the authentic can be defended. So even if contagion effects are rooted in magical thinking, they are not unambiguously irrational factors which lead us astray from correct judgements about art.

Artistic Value and the Ontological Factor of Uniqueness

Uniqueness refers to the belief that ‘original art objects are unique and thus, by definition, are a scarce commodity’. The effect of uniqueness is most readily recognised in the ordinary preference for original artworks over copies. Yet, one might also wonder whether this ordinary preference is truly driven by an ontological factor – the numeric rarity of an artwork – as opposed to a causal-historical factor, such as contagion. After all, the originals may be seen as containing an essence not contained by the copies. In that respect, contemporary art arguably provides excellent examples for disentangling uniqueness from contagion: there exist many works that have multiple authentic editions or instances rather than mere copies.

The effect of uniqueness on the evaluation of art has also been studied in the lab. Uniqueness was found to influence judgements about the monetary value of a work. Moreover, uniqueness was found to interact with contagion, such that ‘the effect of high versus low contact [that is, contagion] was much larger when there was only one original compared with when there were 100 [that is, uniqueness]’. Despite this result, it remains an open question whether uniqueness – and, indeed, contagion – affects people’s judgements of artistic value. The question remains open because it is unknown whether people’s judgements of monetary value truly reflect their own judgements of artistic value. Perhaps they do, but it might also be that judgements of the monetary value of works of art float free of judgements of artistic quality; that is, they may reflect estimates about what is financially valued by others rather than what is valued as art by oneself.

Artistic Value and the Contextual Factor of the Appreciative Environment

Contextualism in philosophy of art is standardly defined by a focus on the context of artistic production:

Contextualism is the thesis that a work of art is an artefact of a particular sort, an object or structure that is the product of human invention at a particular time and place, by a particular individual or individuals, and that that fact has consequences for
how one properly experiences, understands, and evaluates works of art. But that is not the only potentially relevant context in the realm of art. There are also the contexts – including physical, historical, artistic – in which audiences encounter works of art. In particular, given a contemporary picture of cognition on which the mind is ‘not incidentally but intimately embodied and intimately embedded in its world’, we have reasons to think that the environment can influence psychological processes of artistic evaluation. Yet, it is relatively recent that psychologists of art have recognised the significance of the contextual factor of the appreciative environment in theorising about artistic evaluation.

In the last couple of decades, only a small number of studies on art have been done in situ, such as in a museum, as opposed to in the lab. In general, participants evaluate art more positively in situ, as compared to in the lab. Researchers have identified the following factors as potentially explaining this difference: immediacy and physical presence, (perceived) physical remnants of artists’ touch and effort, perceived authenticity, categorising the objects as ‘art’, and size.

There are many challenges to conducting studies in a museum. In a lab, it is relatively easy to ethically implement experimental manipulations, secure access to a participant pool (traditionally, college-age students), and recruit enough participants for adequate power. All three factors are relatively difficult to execute in a museum. As such, some museum studies are only observational. And many museum studies still use traditional but unrepresentative college-age students as participants. Finally, many museum studies are relatively underpowered by today’s standards.

STUDY 1: IN SITU
Theoretical Rationale
To study the influence of contagion and uniqueness on artistic evaluation in situ, we conducted an experiment during Grayson Perry’s The Vanity of Small Differences exhibit at Temple Newsam House in Leeds, UK. Temple Newsam House was a somewhat unusual venue for this exhibit because it was originally built as a country house, not a ‘white cube’ gallery or art museum. There was thus a special interest in the interplay between Perry’s contemporary tapestries and its 19th century environment for artistic appreciation. However, for the purpose of our experiment, the venue was unambiguously used for the art exhibit, and thus constitutes an in situ context of appreciation.

Like many other contemporary artists, Perry did not physically make the works that are credited to him. Instead, for the tapestries in this exhibit, he designed the image on the computer and then sent the files to a manufacturer in Flanders, where other people programmed computers that controlled the
looms, sourced and dyed the yarns, and laced the looms. For studying the
effect of contagion, we investigated whether this information about the works’
causal history influenced exhibit visitors’ artistic evaluations. We predicted
that it would.

Like many other contemporary artworks, multiple editions of the tapestries
exist.24 For each design of the tapestries, eight instances were made: six for
display and two for artist’s proofs. Unlike many other objects in art muse-
umums, Perry’s tapestries are not literally one of a kind. (Still, Perry was also
adamant that only one edition of a design can be shown in any given exhibit.)
For studying the effect of uniqueness, we investigated whether this informa-
tion about the works’ ontological status influenced exhibit visitors’ artistic
evaluations. Again, we predicted that it would.

Participants
A total of 286 adult visitors who paid the standard museum entrance fee
participated in this study. They were given a small gift related to the exhibit
in exchange for their participation in this study. 76 visitors self-identified as
men, 195 self-identified as women, 1 self-identified as trans, and 14 did not
respond to the gender question. Only 19 participants did not self-report their
age; of the ones who did, the mean was 47.3 years, the median was 52 years,
and the minimum and maximum were 18 years and 79 years.

Participants were randomly assigned into one of two conditions. 144 par-
ticipants were in the experimental condition, in which information about the
causal history and ontological status of Perry’s tapestries was given prior to
questions about their artistic value. 142 participants were in the control con-
dition, in which information about the causal history and ontological status
of Perry’s tapestries was given after questions about their artistic value.

Procedure and Materials
Participants viewed six tapestries by Grayson Perry in situ, in the intended
order of the exhibit: 1. The Adoration of the Cage Fighters, 2. The Agony in
the Car Park, 3. Expulsion from Number 8 Eden Close, 4. The Annunciation
of the Virgin Deal, 5. The Upper Class at Bay, 6. #Lamentation.

Before they entered the exhibit, participants received a paper question-
naire packet to complete. Participants were explicitly instructed to ‘go through
this questionnaire packet page by page, and do not return to the previous
page after you have moved on to the next one’.

In the experimental condition, participants received the following informa-
tion at the start (all emphases are reproduced as they were in the materials):

Grayson Perry initially designed each of the six tapestries in Photo-
shop.

Each of the six tapestries were then woven by computer-
operated machinery at the Flanders Tapestries in Belgium.
Perry’s computer files were adapted for programming the computers that control the looms. With the design finalised, the actual process of weaving each tapestry then took about 5 hours.

**Eight identical copies of each tapestry were then produced.**

In the control condition, participants received the same exact information, but only at the end of the packet. Note that since our aim was to conduct this experiment as part of – and without detracting from – visitors’ ordinary museum-going experience, we were only able to experimentally manipulate information order as a difference in emphasis; the information given about causal history and ontological status can also be found online and, albeit in smaller print, as part of the exhibit.

Participants were asked for their artistic evaluations for each of the six tapestries. Participants circled their response to the statement

**This tapestry is of high artistic quality**

on a 7-point agree-disagree scale. Participants were given an image of the tapestry in the questionnaire packet for reference.

Participants then responded to statements about the exhibit in the following order. First, there were statements related to contagion:

- Each tapestry embodies Grayson Perry’s very being.
- Each tapestry contains the true essence of Grayson Perry.
- Each tapestry gets its special aura from Grayson Perry.

Second, there were statements related to uniqueness:

- Each tapestry on display is very rare for an artwork.
- Each tapestry on display is very scarce.
- Each tapestry on display is unique.

Participants also responded to these questions on a 7-point agree-disagree scale. Finally, participants responded to demographic questions. In addition to standard questions about age and gender, participants also responded to questions about their level of experience with art on a 7-point scale:

- How often do you go to art museums, art galleries, and art exhibitions?
- How interested are you in contemporary art?
- How educated are you in the fine arts?

And participants also responded to questions about their prior knowledge of the exhibit on a 7-point scale:
How much did you know about Grayson Perry before this exhibit?
How much did you know about the production of tapestries?

We note that we asked the experience and knowledge questions in order to better understand our sample demographic and in order to control for potential factors outside of the ones that we were primarily investigating: the causal-historical factor of contagion and the ontological factor of uniqueness. As such, we did not make any predictions about the influence of experience and knowledge on artistic evaluation.

Preliminary Analyses and Discussion
Reliability analyses were performed on participant responses. There was very strong agreement on participants’ artistic evaluations of the six tapestries (Cronbach’s $\alpha = 0.970$), and so they were averaged into an artistic evaluation rating for subsequent analyses. There was strong agreement on participants’ responses to contagion questions (Cronbach’s $\alpha = 0.852$), and so they were averaged into a contagion rating for subsequent analyses. There was strong agreement on participants’ responses to uniqueness questions (Cronbach’s $\alpha = 0.706$), and so they were averaged into a uniqueness rating for subsequent analyses. For the two extrinsic factors of interest, we chose to ask about them in a few different ways to better capture the psychological construct, even though we realise that the exact phrases might involve subtle conceptual differences. The reliability analyses suggest that there are indeed stable psychological constructs that are captured by the different ways of asking about the extrinsic factors.

In addition, there was strong agreement on participants’ responses to questions about their level of experience with art (Cronbach’s $\alpha = 0.786$), and so they were averaged into an experience with art rating for subsequent analyses. However, there was only moderate agreement on participants’ responses to questions about their prior knowledge of the exhibit (Cronbach’s $\alpha = 0.653$), and so the two questions were treated as separate for subsequent analyses.

As we have noted, given the constraints of conducting a study in situ, we were only able to include a weak experimental manipulation as a matter of emphasis. Our own subjective impression was that the experimental manipulation was not very successful, in the relatively uncontrolled environment: we observed some participants ignoring the explicit instruction of going through the packet page and page and not turn back. Indeed, statistical analyses confirmed our subjective impression. For contagion, the difference between the experimental group ($M = 4.90; SD = 1.50$) and the control group ($M = 5.19; SD = 1.38$) is not statistically significant ($p = 0.094$; Cohen’s $d = 0.202$). For uniqueness, the difference between the experimental group ($M = 4.97; SD = 1.59$) and the control group ($M = 5.36; SD = 1.46$) is statistically significant but small ($p = 0.034$; Cohen’s $d = 0.256$).
Main Analysis and Discussion

Given that the experimental manipulation was not very successful, we analysed the data set in its entirety and focused on uncovering the relationships between participants’ perceptions of contagion and uniqueness and their artistic evaluations. We specified a linear mixed model for the main analysis: *artistic evaluation* was defined as the dependent variable; *contagion, uniqueness*, and their interaction were examined as fixed effects; and the demographic variables of experience with art, prior knowledge about Perry, and prior knowledge about tapestry were treated as random effects.

*Table 1. Parameter Estimates for the Linear Mixed Model in Study 1.*

The main results of our in situ study partly coheres with, but also partly contradicts, previous lab study findings (Table 1). In congruence with previous lab study findings and our own prediction, we found a direct relationship between contagion and artistic evaluation (*p* < 0.001). That is, to the extent that participants thought that the tapestries took on Perry’s essence, they made more positive artistic judgements of the tapestries. However, contrary to previous lab study findings and our own prediction, we did not find a relationship between uniqueness and artistic evaluation (*p* = 0.201) and we did not find an interaction between contagion and uniqueness (*p* = 0.713). That is, it does not appear that participants’ thoughts of the uniqueness of the tapestries – either by itself or in combination with participants’ thoughts on contagion – affected their artistic judgements of the tapestries. We will return to hypothesise about these results in the general discussion.

**STUDY 2: IN THE LAB**

**Theoretical Rationale**

We wondered whether the discrepancy between the results of our in situ study and the results of extant lab research, with respect to the ontological factor of uniqueness, is due to the difference in the appreciative environment. As such, we sought to investigate this contextual factor with a follow-up study online in which participants viewed the same artworks and answered the same questions.

**Participants**

A total of 199 participants were recruited via Amazon Mechanical Turk in exchange for standard market-rate monetary compensation. Participation
was restricted to those whose computer’s geographical location was identified as being in the United States of America. 106 participants self-identified as men, 92 self-identified as women, and 1 did not respond. Only 3 participants did not self-report their age; of the ones who did, the mean was 34.2 years, the median was 31 years, and the minimum and maximum were 18 years and 68 years.

In the same setup as Study 1, participants were randomly assigned into one of two conditions. 100 participants were in the experimental condition. 99 participants were in the control condition.

Procedure and Materials
Participants answered the exact same questions, with the exact same manipulation, as implemented in Qualtrics. Participants viewed digital reproductions of the tapestries as components of the questionnaire itself.

Preliminary Analyses and Discussion
Reliability analyses were performed on participant responses along several dimensions. There was very strong agreement on participants’ artistic evaluations of the six tapestries (Cronbach’s $\alpha = 0.920$), and so they were averaged into an artistic evaluation rating for subsequent analyses. There was strong agreement on participants’ responses to contagion questions (Cronbach’s $\alpha = 0.838$), and so they were averaged into a contagion rating for subsequent analyses. There was only a moderate agreement on participants’ responses to uniqueness questions (Cronbach’s $\alpha = 0.603$), but they were – in order to facilitate comparisons to Study 1 – still averaged into a uniqueness rating for subsequent analyses. There was strong agreement on participants’ responses to questions about their level of experience with art (Cronbach’s $\alpha = 0.769$), and so they were averaged into an experience with art rating for subsequent analyses. However, there was only moderate agreement on participants’ responses to questions about their prior knowledge of the exhibit (Cronbach’s $\alpha = 0.618$), and so the two questions were treated as separate for subsequent analyses.

Again, in order facilitate comparisons to Study 1, we used the same experimental manipulation. The online questionnaire was programmed such that participants could not return to modify their answers once they moved on from one section (for example, artistic evaluation statements) to another (for example, contagion and uniqueness statements). Unfortunately, contrary to our expectation, the experimental manipulation was still unsuccessful. For contagion, the difference between the experimental group ($M = 4.95; SD = 1.16$) and the control group ($M = 4.96; SD = 1.07$) was not statistically significant ($p = 0.935$). For uniqueness, the difference between the experimental group ($M = 4.87; SD = 1.16$) and the control group ($M = 4.99; SD = 1.09$) was not statistically significant ($p = 0.428$). These preliminary analyses results suggest that the experimental manipulation was too weak: in our
studies, participants were either given factual information about historical and ontological sources of value or not; by contrast, in previous experiments participants were given drastically different information, such as being told about a hands-on vs. hands-off process (for contagion) and about 1 vs. 100 sculptures (for uniqueness).²⁶

Main Analysis and Discussion

Given that the experimental manipulation was not successful, we once again analysed the data set in its entirety and focused on uncovering the relationships between participants’ perceptions of contagion and uniqueness and their artistic evaluations. We specified a linear mixed model identical to the one used for Study 1.

Table 2. Parameter Estimates for the Linear Mixed Model in Study 2.

The main results of our online study were overall more in line with previous lab study findings, and less in line with our in situ study (Table 2). We again found a relationship between contagion and artistic evaluation \( p = 0.009 \). That is, to the extent that participants thought that the tapestries took on Perry’s essence, they made more positive artistic judgements of the tapestries. However, in this study, in congruence with previous studies, we also found a relationship between uniqueness and artistic evaluation \( p < 0.001 \). That is, to the extent that participants thought that the tapestries were unique, they made more positive artistic judgements of the tapestries. In contrast to previous lab studies, we did not find an interaction between contagion and uniqueness \( p = 0.887 \). That is, participants’ thoughts about contagion and their thoughts about uniqueness appear to independently influence their artistic judgements. Given these more nuanced, but no less puzzling, results, we will look across both studies and hypothesise about salient differences in the general discussion.

GENERAL DISCUSSION

Artistic Value and the Causal-Historical Factor of Contagion

Across our studies, we found a positive relationship between people’s perception of the artist’s contact with an artwork and their artistic evaluation of that work. In this respect, our studies affirmed previous lab study findings on contagion in particular, and magical thinking in general. However, our
studies also go beyond previous ones in two important respects. First, previous studies were primarily conducted in the context of consumer research, and so focused on judgements about monetary value; by contrast, our studies explicitly focused on judgements of artistic value, and so extends the study of this extrinsic factor into a related, but plausibly distinct, psychological domain. Second, previous studies were conducted in a lab, and so our in situ study adds to the ecological validity of the psychological phenomenon.

Of philosophical significance, our empirical findings cohere with an important recent account that emphasises the aesthetic and artistic significance of authenticity. As mentioned earlier, Korsmeyer argues that the experience of genuineness (that is, ‘being the real thing’) is an aesthetic experience rooted in the sense of touch. Moreover, the fact that we value such experiences – as evidenced in the common preference for authentic artefacts over perceptually indistinguishable replicas – is, she argues, not irrational. That is, despite the fact that our concern for the genuine seems rooted in apparently irrational factors such as the ‘transitivity of touch’ and ‘magical thinking’, that concern is defensible. The effect of contagion, on Korsmeyer’s view, might be explained by ordinary processes of cognitive penetration and its functional similarity to other non-fungible emotions. While our studies do not speak to the rationality or appropriateness of valuing authenticity, they do provide some empirical support for Korsmeyer’s claims that authenticity commonly affects artistic evaluation.

**Artistic Value and the Ontological Factor of Uniqueness**

Unlike the case with contagion, our studies delivered mixed results on uniqueness. While we found in the lab setting a positive relationship between people’s perception of an artwork’s uniqueness and their artistic evaluation of that work, we did not find such a relationship in the museum setting. These mixed results could be, as we have acknowledged, explained away as a mere artefact of our weak experimental manipulation. Or they could be due to a discrepancy between previous studies’ focus on monetary value as opposed to artistic value. Or they could be explained by a difference in the context of appreciation – a possibility that we will explore shortly. Given the number of possible explanations, we caution against drawing any strong inference about this extrinsic source of value.

**Artistic Value and the Contextual Factor of the Appreciative Environment**

Comparing the results of our studies also prompted us to hypothesise about the effect that context of appreciation has on other extrinsic factors and artistic value. Remember that Grayson Perry was adamant that only one edition of a design can be shown in any given exhibit. Our museum study suggests that he might not need to be so worried about the effects of undermining
the tapestry’s perceived uniqueness. Perhaps factors identified in previous studies on the difference between appreciating art in situ and in the lab, such as immediacy and physical presence, overwhelm the effect of uniqueness, such that it only shows up in the lab but not in the museum.\textsuperscript{28}

Or perhaps the difference in our studies’ results are better explained by a corresponding difference in participant characteristics. In a post hoc exploratory analysis, we found a large difference with respect to the level of experience with art ($M_{\text{museum}} = 4.62$, $SD_{\text{museum}} = 1.44$; $M_{\text{lab}} = 3.16$, $SD_{\text{lab}} = 1.31$; Welch’s $t(449) = 11.588$, $p < 0.001$, Cohen’s $d = 1.094$). So the non-unique nature of Perry’s tapestries might stand out much more for participants with a low level of experience with art – and, hence, have a greater effect their judgements of value – than for participants with a relatively high level of experience. This result is intriguing and may be congruent with previous studies which found that art expertise influences affective and, hence, aesthetic evaluation, but since we did not focus on experience or knowledge in the design of our study, it would be unreasonable to conclude much about those \textit{ex post facto}.\textsuperscript{29}

\section*{Philosophical and Practical Upshots}

As described above, experimental research on the arts and aesthetic matters has largely been confined to the lab. Although things are beginning to change, it is still the case that the vast majority of such work takes place outside the standard contexts in which we experience art. Experimental philosophical aesthetics, an emerging sub-discipline of philosophy which includes this paper, is no different; most work in the area to this date has been done in the lab.\textsuperscript{30} Our studies provide further evidence that in situ aesthetic research (that is, in the gallery or museum or concert hall or theater) is both possible and productive. Moreover, our results suggest that it may be important to do that in situ research because the context of appreciation may be a significant factor in artistic evaluation.

To the extent that philosophical aestheticicians draw on experimental psychological evidence in their theorising, they should be attentive to the ecological validity of findings and be supportive of empirical research beyond the lab. Although philosophers have certainly been aware of the potential significance of the context of artistic evaluation, further focus on empirical findings may help them to refine their psychological models, especially from the perspective of the embodied and embedded mind.

Our studies also suggest that philosophers should take more seriously the role of contagion in artistic evaluation, especially given the ecological validity of the psychological effect. Those who claim that this effect on evaluation is irrational or irrelevant need to explain, or explain away, this phenomenon. Indeed, we think our results provide some support for philosophical accounts that attempt to vindicate people’s concern for authenticity in art.\textsuperscript{31}
Finally, we hope our results hold interest not just for philosophers and psychologists, but museum professionals as well. For example, thinking about how different causal-historical and ontological factors may affect museum-goers’ artistic evaluations might inform museum professionals about the kind of information they want to provide for their audience. In fact, in exploring the significance of the context of appreciation, we hope to have provided some support to the idea — surely familiar to these professionals — that there is indeed something special about appreciating art in the museum.
